Outline

- Structure of Relational Databases
- Database Schema
- Keys
- Schema Diagrams
- Relational Query Languages
- The Relational Algebra

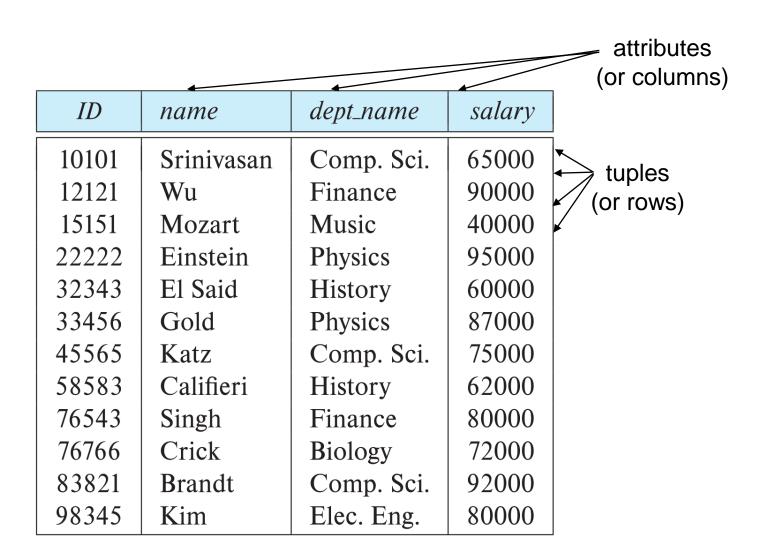

Relational Database

- A relational database consists of a collection of tables, each of which is assigned a unique name
- In the relational model the term relation is used to refer to a table
- The term tuple is used to refer to a row
- The term attribute refers to a column of a table

Example of a *Instructor* Relation

Relation Schema and Instance

- $A_1, A_2, ..., A_n$ are attributes
- $R = (A_1, A_2, ..., A_n)$ is a relation schema Example:

instructor = (ID, name, dept_name, salary)

- The term relation instance to refer to a specific instance of a relation, i.e., containing a specific set of rows
- A relation instance r defined over schema R is denoted by r(R).
- An element t of relation r is called a tuple and is represented by a row in a table

Attributes

- The set of allowed values for each attribute is called the domain of the attribute
- Attribute values are (normally) required to be atomic; that is, indivisible
- The special value *null* is a member of every domain. Indicated that the value is "unknown"
- The null value causes complications in the definition of many operations

Relations are Unordered

- Order of tuples is irrelevant (tuples may be stored in an arbitrary order)
- Example: instructor relation with unordered tuples

ID	name	dept_name	salary
22222	Einstein	Physics	95000
12121	Wu	Finance	90000
32343	El Said	History	60000
45565	Katz	Comp. Sci.	75000
98345	Kim	Elec. Eng.	80000
76766	Crick	Biology	72000
10101	Srinivasan	Comp. Sci.	65000
58583	Califieri	History	62000
83821	Brandt	Comp. Sci.	92000
15151	Mozart	Music	40000
33456	Gold	Physics	87000
76543	Singh	Finance	80000

Database Schema

- Database schema -- is the logical structure of the database.
- Database instance -- is a snapshot of the data in the database at a given instant in time.
- Example:
 - schema: instructor (ID, name, dept_name, salary)
 - Instance:

ID	name	dept_name	salary
22222	Einstein	Physics	95000
12121	Wu	Finance	90000
32343	El Said	History	60000
45565	Katz	Comp. Sci.	75000
98345	Kim	Elec. Eng.	80000
76766	Crick	Biology	72000
10101	Srinivasan	Comp. Sci.	65000
58583	Califieri	History	62000
83821	Brandt	Comp. Sci.	92000
15151	Mozart	Music	40000
33456	Gold	Physics	87000
76543	Singh	Finance	80000

Keys

- Superkey is a set of one or more attributes that, taken collectively, allow us to identify uniquely a tuple in the relation
- Let K ⊂ R
- K is a superkey of R if values for K are sufficient to identify a unique tuple of each possible relation r(R)
 - Example: {ID} and {ID,name} are both superkeys of instructor.
- Superkey K is a candidate key if K is minimal Example: {ID} is a candidate key for Instructor
- Primary key: one of the candidate keys is selected by the database designer as the principal means of identifying tuples within a relation.
- The primary key should be chosen such that
 - must be a unique identifier and not null
 - its attribute values are never, or very rarely, changed

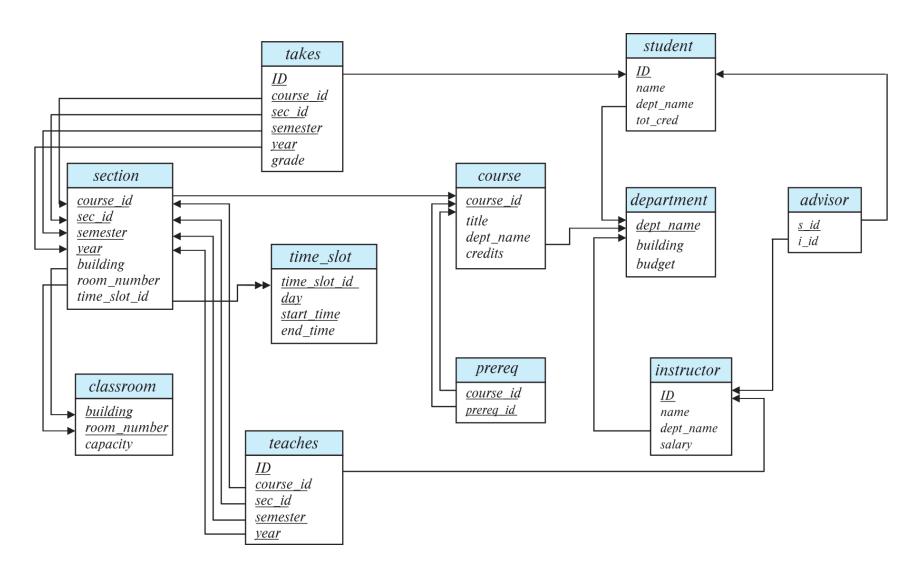

Foreign Keys

- A foreign key is an attribute (or a set of attributes) in a relation that refers to the primary key of another relation. The foreign key links these two relations.
- Foreign key constraint: Value in one relation must appear in another
 - Example: dept_name in instructor is a foreign key from instructor relation referencing department relation
 - Referencing relation: instructor
 - Referenced relation: department

Schema Diagram for University Database

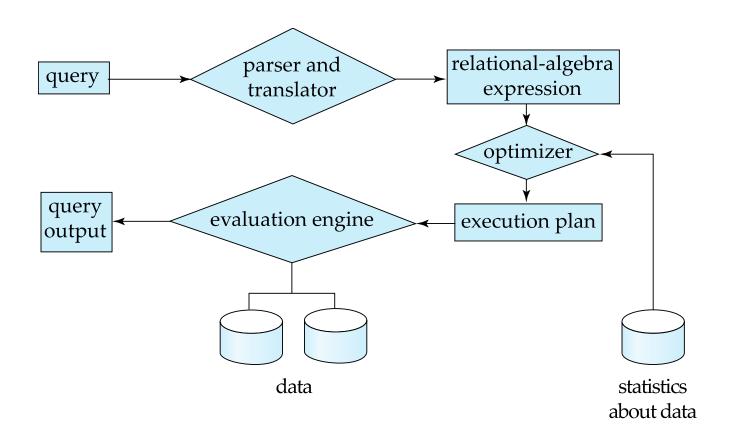

Relational Query Languages

- Procedural versus non-procedural, or declarative
- "Pure" languages:
 - Relational algebra (Procedural)
 - Tuple relational calculus (Non-procedural)
 - Domain relational calculus (Non-procedural)
- The above 3 pure languages are equivalent in computing power
- We will concentrate in this chapter on relational algebra
 - Not Turing-machine equivalent
 - Consists of 6 basic operations

Role of Relational Algebra

Relational Algebra

- A procedural language consisting of a set of operations that take one or two relations as input and produce a new relation as their result.
- Six basic operators
 - select: σ
 - project: ∏
 - union: ∪
 - set difference: –
 - Cartesian product: x
 - rename: ρ

Select Operation

- The select operation selects tuples that satisfy a given predicate.
- Notation: $\sigma_p(r)$
- p is called the selection predicate
- Example: select those tuples of the instructor relation where the instructor is in the "Physics" department.
 - Query

Result

ID	name	dept_name	salary
22222	Einstein	Physics	95000
33456	Gold	Physics	87000

Select Operation (Cont.)

We allow comparisons using

in the selection predicate.

• We can combine several predicates into a larger predicate by using the connectives:

$$\wedge$$
 (and), \vee (or), \neg (not)

Example: Find the instructors in Physics with a salary greater \$90,000, we write:

$$\sigma_{dept_name="Physics"} \land salary > 90,000 (instructor)$$

- The select predicate may include comparisons between two attributes.
 - Example, find all departments whose name is the same as their building name:
 - σ_{dept_name=building} (department)

Project Operation

- A unary operation that returns its argument relation, with certain attributes left out.
- Notation:

$$\prod_{A_1,A_2,A_3,\ldots,A_k} (r)$$

where $A_1, A_2, ..., A_k$ are attribute names and r is a relation name.

- The result is defined as the relation of k columns obtained by erasing the columns that are not listed
- Duplicate rows removed from result, since relations are sets

Project Operation Example

- Example: eliminate the dept_name attribute of instructor
- Query:

 $\prod_{ID, name, salary}$ (instructor)

Result:

ID	name	salary
10101	Srinivasan	65000
12121	Wu	90000
15151	Mozart	40000
22222	Einstein	95000
32343	El Said	60000
33456	Gold	87000
45565	Katz	75000
58583	Califieri	62000
76543	Singh	80000
76766	Crick	72000
83821	Brandt	92000
98345	Kim	80000

Composition of Relational Operations

- The result of a relational-algebra operation is relation and therefore of relational-algebra operations can be composed together into a relational-algebra expression.
- Consider the query -- Find the names of all instructors in the Physics department.

$$\prod_{name} (\sigma_{dept \ name = "Physics"} (instructor))$$

 Instead of giving the name of a relation as the argument of the projection operation, we give an expression that evaluates to a relation.

Cartesian-Product Operation

- The Cartesian-product operation (denoted by X) allows us to combine information from any two relations.
- Example: the Cartesian product of the relations instructor and teaches is written as:

instructor X teaches

- We construct a tuple of the result out of each possible pair of tuples: one from the instructor relation and one from the teaches relation (see next slide)
- Since the instructor ID appears in both relations we distinguish between these attribute by attaching to the attribute the name of the relation from which the attribute originally came.
 - instructor.ID
 - teaches.ID

The instructor x teaches table

Join Operation

The Cartesian-Product

instructor X teaches

associates every tuple of instructor with every tuple of teaches.

- Most of the resulting rows have information about instructors who did NOT teach a particular course.
- To get only those tuples of "instructor X teaches" that pertain to instructors and the courses that they taught, we write:

```
\sigma_{instructor.id = teaches.id} (instructor x teaches))
```

We get only those tuples of "instructor X teaches" that pertain to instructors and the courses that they taught.

The result of this expression, shown in the next slide

Join Operation (Cont.)

The table corresponding to:

 $\sigma_{instructor.id = teaches.id}$ (instructor x teaches))

Join Operation (Cont.)

- The join operation allows us to combine a select operation and a Cartesian-Product operation into a single operation.
- Consider relations r (R) and s (S)
- Let "theta" be a predicate on attributes in the schema R "union" S. The join operation $r \bowtie_{\theta} s$ is defined as follows:

$$r \bowtie_{\theta} s = \sigma_{\theta} (r \times s)$$

Thus

$$\sigma_{instructor.id = teaches.id}$$
 (instructor x teaches))

Can equivalently be written as

instructor ⋈ _{Instructor.id} = _{teaches.id} teaches.

Union Operation

- The union operation allows us to combine two relations
- Notation: $r \cup s$
- For r ∪ s to be valid.
 - 1. *r*, *s* must have the *same* **arity** (same number of attributes)
 - 2. The attribute domains must be **compatible** (example: 2nd column of *r* deals with the same type of values as does the 2nd column of *s*)
- Example: to find all courses taught in the Fall 2017 semester, or in the Spring 2018 semester, or in both

$$\Pi_{course_id}(\sigma_{semester="Fall" \land year=2017}(section)) \cup \Pi_{course_id}(\sigma_{semester="Spring" \land year=2018}(section))$$

Union Operation (Cont.)

Result of:

$$\Pi_{course_id}(\sigma_{semester="Fall" \land year=2017}(section)) \cup \Pi_{course_id}(\sigma_{semester="Spring" \land year=2018}(section))$$

course_id

CS-101

CS-315

CS-319

CS-347

FIN-201

HIS-351

MU-199

PHY-101

Set-Intersection Operation

- The set-intersection operation allows us to find tuples that are in both the input relations.
- Notation: $r \cap s$
- Assume:
 - r, s have the same arity
 - attributes of r and s are compatible
- Example: Find the set of all courses taught in both the Fall 2017 and the Spring 2018 semesters.

$$\prod_{course_id} (\sigma_{semester="Fall" \land year=2017}(section)) \cap \prod_{course_id} (\sigma_{semester="Spring" \land year=2018}(section))$$

Result

course_id
CS-101

Set Difference Operation

- The set-difference operation allows us to find tuples that are in one relation but are not in another.
- Notation r s
- Set differences must be taken between compatible relations.
 - r and s must have the same arity
 - attribute domains of r and s must be compatible
- Example: to find all courses taught in the Fall 2017 semester,
 but not in the Spring 2018 semester

$$\prod_{course_id} (\sigma_{semester="Fall" \land year=2017}(section)) - \prod_{course_id} (\sigma_{semester="Spring" \land year=2018}(section))$$

Result

course_id
CS-347
PHY-101

The Assignment Operation

- It is convenient at times to write a relational-algebra expression by assigning parts of it to temporary relation variables.
- The assignment operation is denoted by ← and works like assignment in a programming language.
- Example: Find all instructor in the "Physics" and Music department.

```
Physics \leftarrow \sigma_{dept\_name="Physics"} (instructor)

Music \leftarrow \sigma_{dept\_name="Music"} (instructor)

Physics \cup Music
```

With the assignment operation, a query can be written as a sequential program consisting of a series of assignments followed by an expression whose value is displayed as the result of the query.

The Rename Operation

- The results of relational-algebra expressions do not have a name that we can use to refer to them. The rename operator, ρ, is provided for that purpose
- The expression:

$$\rho_{X}(E)$$

returns the result of expression *E* under the name *x*

Another form of the rename operation:

$$\rho_{x(A1,A2,..An)}(E)$$

Equivalent Queries

- There is more than one way to write a query in relational algebra.
- Example: Find information about courses taught by instructors in the Physics department with salary greater than 90,000
- Query 1

```
\sigma_{dept\_name="Physics"} \land salary > 90,000 (instructor)
```

Query 2

```
\sigma_{dept\_name="Physics"}(\sigma_{salary>90.000}(instructor))
```

The two queries are not identical; they are, however, equivalent
 they give the same result on any database.

Equivalent Queries

- There is more than one way to write a query in relational algebra.
- Example: Find information about courses taught by instructors in the Physics department
- Query 1

```
\sigma_{dept\_name="Physics"} (instructor \bowtie_{instructor.ID=teaches.ID} teaches)
```

Query 2

```
(\sigma_{dept\ name="Physics"}(instructor)) \bowtie_{instructor.ID=teaches.ID} teaches
```

The two queries are not identical; they are, however, equivalent -- they give the same result on any database.

End of Chapter 2
